Radiation detection modules

C12137 series

High accuracy, high sensitivity, compact radiation detection module

The C12137 series is a radiation detection module containing a scintillator and MPPC® (multi-pixel photon counter) designed to detect gamma rays from $^{137}$Cs (Cesium-137) and the like. The scintillator converts incident gamma rays into visible light, and the MPPC detects the light down to extremely low light levels to measure low-energy gamma rays with high accuracy. The signal processing circuit and A/D converter are housed in a compact case. The modules provide a USB or RS-232C interface. The products include sample software with functions for setting measurement conditions, acquiring and saving data, and drawing graphs, etc.

Features

- Gamma ray energy discrimination
- Modular design for easy integration into devices
- Compact and lightweight

Applications

- Environmental monitoring and mapping
- Gamma ray energy discrimination
- Incorporation into portable, high-sensitivity detectors
- Screening such as incoming and outgoing inspections at manufacturing sites

Lineup

A total of eight types in four different sizes and two interfaces (USB and RS-232C) are available that you can choose from according to your application.

* The characteristics are the same between the USB type and RS-232C type (the software specifications are different).

*2: Measurement range of these products is defined by 137Cs. When detecting environmental radiation that mainly consists of low energy radiation, the maximum measurement value will be approx. 1/3 to 1/2 of this figure.

*3: C12137-08/-08D/-10/-10D do not perform conversion into dose rate using the G(E) function.

## Block diagram (C12137)

![Block diagram of C12137](diagram.png)
The C12137 series can acquire energy spectra and therefore can perform energy discrimination. $^{137}$Cs is known to decay while emitting gamma rays at energies around 662 keV and 32 keV. The C12137/-01 can determine whether gamma rays is from $^{137}$Cs by acquiring the energy spectrum from the low-energy gamma rays at around 30 keV. As the gamma rays become lower in energy, the level of light emitted by the scintillator weakens. However, the Radiation detection module, which uses a high sensitivity MPPC, is able to detect gamma rays over a wide range from low-energy gamma rays around 30 keV up to about 2 MeV.$^5$

The low-light-level detection performance of high gain MPPCs also contributes greatly to reducing the measurement time. To reduce the measurement time, the scintillator capacity must be increased to improve the detection efficiency. However, as the scintillator capacity is increased, the level of light that reaches the photosensor is attenuated inside the scintillator, and the lower limit of detection degrades accordingly. This makes it more difficult to detect low energy gamma rays. The MPPC offers higher gain than the PIN photodiode or APD and makes low-light-level detection possible. Even when it is combined with a large capacity scintillator, low-energy gamma rays can still be measured.

$^4$: The lower limit of the energy range of the C12137-08/-10 is 60 keV.
$^5$: C12137/-01

**Feature 02 Easy integration in devices**

Since the radiation detection module includes a scintillator, photosensor (MPPC), signal processing circuit, interface circuit, and the like in a small case, it can easily be incorporated into portable measuring instruments and in-line measuring instruments.

In the C12137 series, the photosensor MPPC is a small, thin type. The MPPC takes up a small portion of the entire space: the space is predominantly taken up by the scintillator. This shows that even though the radiation detection module is small, it can provide high photon detection efficiency. Because the radiation detection module is compact, it is advantageous in applications where the radiation dose from the object under measurement is minute. Such applications include inspection of food and beverages. In these types of applications, the periphery of the detector must be covered with lead to eliminate the effects of environmental radiation. Because the radiation detection module is compact, the amount of used lead can be reduced, which in turn reduces the volume and weight of the entire device.

**Feature 03 Superb temperature stability**

The level of emitted light by the scintillator due to incident gamma rays and the photosensor sensitivity are temperature dependent. This temperature dependence causes a shift in the detected energy when the ambient temperature changes even when gamma rays with the same energy are incident and ultimately causes measurement errors and interferes with radionuclide identification. The gamma ray detector unit of the C12137 series employs a structure with high temperature stability as well as a temperature-compensation circuit, which exhibits excellent temperature stability even when the temperature changes drastically. The graph below illustrates the detected energy shift of the C12137 in response to ambient temperature changes. The temperature stability is ±5% max. in the ambient temperature range of 0 to +50 °C.
Sample software

The C12137 series comes with sample evaluation software for initial evaluation. The software provides basic functions for setting measurement conditions, acquiring and saving data, and drawing graphs\(^5\), etc. To help you develop your own application software for operating the radiation detection module integrated in your equipment, function specifications and sample software source code are also provided.

Precautions

- These products are precision devices that use a scintillator and are not designed to be used outdoors or in locations subject to vibration or shock. To use them in such an environment, you will need to incorporate appropriate measures in the design.

Accessories

- USB cable
- CD-ROM (instruction manual, sample software)
